- ☐ Elementary Statistics, 13<sup>th</sup> Edition, Mario F. Triola

### Reference books

- ☐ Probability Demystified, Allan G. Bluman
- ☐ Schaum's Outline of Probability and Statistics
- ☐ MATLAB Primer, Seventh Edition
- ☐ MATLAB Demystified by McMahon, David

### References

Readings for these lecture notes:

- □ Probability & Statistics for Engineers & Scientists,
  Ninth edition, Ronald E. Walpole, Raymond H.
  Myer
- □ Elementary Statistics, 10<sup>th</sup> Edition, Mario F. Triola
- □ Probability Demystified, Allan G. Bluman

These notes contain material from the above three books.

"Failure will never overtake me if my determination to succeed is strong enough."

**Og Mandino** 

### **Binomial Distribution [1]**

A binomial distribution is obtained from a probability experiment called a binomial experiment. The experiment must satisfy these conditions:

- Each trial can have only two outcomes or outcomes that can be reduced to two outcomes.
   The outcomes are usually considered as a success or a failure.
- 2. There is a **fixed number** of trials.
- 3. The outcomes of each trial are **independent** of each other.
- 4. The probability of a **success** must remain the **same** for each trial.

### **Binomial Distribution [3]**

**EXAMPLE:** Explain why the probability experiment of tossing three coins is a binomial experiment.

### **Binomial Distribution [2]**

- 1. There are only **two outcomes** for each trial, head and tail. Depending on the situation, either heads or tails can be defined as a success and the other as a failure.
- 2. There is a **fixed number** of trials. In this case, there are three trials since three coins are tossed or one coin is tossed three times.
- The outcomes are independent since tossing one coin does not effect the outcome of the other two tosses.
- 4. The probability of a success (say heads) is  $\frac{1}{2}$  and it does not change. Hence the experiment meets the conditions of a binomial experiment.

## **Binomial Distribution [3]**

The binomial probability formula is used to compute **probabilities** for **binomial** random variables. The binomial probability formula is given as:

$$b(x; n, p) = c_x^n p^x q^{n-x} \text{, } x = 0, 1, 2, ...$$
 where  $c_x^n = \frac{n!}{x!(n-x)!}$ 

$$b(x; n, p) = {n \choose x} p^x q^{n-x}, x = 0, 1, 2, ...$$

where n = the total number of trials

x =the number of successes (0, 1, 2, 3, ..., n)

p = the probability of a success

q = the probability of a failure

### **Binomial Distribution [4]**

**Example:** A coin is tossed three times. Find the probability of getting two heads and a tail in any given order.

## **Binomial Distribution [5]**

#### **Solution:**

Here n = 3

$$p = \frac{1}{2}$$

$$p + q = 1$$

$$q=1-p=1-\frac{1}{2}=\frac{1}{2}$$

(probability of a head)

(probability of a tail)

Let x denotes number of heads

$$b(x; n, p) = {n \choose x} p^x q^{n-x}, x = 0, 1, 2, ...$$

b(2; 3, 0.5) = 
$$\binom{3}{2} (\frac{1}{2})^2 (\frac{1}{2})^{3-2} = 3(\frac{1}{4}) (\frac{1}{2}) = \frac{3}{8}$$

## **Binomial Distribution [5]**

- ☐ It is the case of sampling with replacement.
- $\square$  It has two parameters i.e., **n** and **p**.
- Mean=np, Variance =npq and Standard deviation = sqrt(npq).
- $\Box$  If p = q then the distribution is **symmetrical** irrespective of the value of n.
  - $\square$  If p < 0.5 the distribution is negatively skewed.
  - $\square$  If p > 0.5 then the distribution is **positively** skewed.

### **Binomial Distribution [6]**

The normal distribution (Gaussian distribution) can be regarded as the limiting form of the binomial distribution when n, the of trials is very large and neither p nor q is very small.

Note: Because the normal approximation is not accurate for small values of n, a good rule of thumb is to use the normal approximation only if  $np \ge 10$  and  $np(1-p) \ge 10$ .

# The Mean and Standard Deviation for a Binomial Distribution [1]

**EXAMPLE:** A die is tossed 180 times and the number of threes obtained is recorded. Find the mean or expected number of threes.

# The Mean and Standard Deviation for a Binomial Distribution [2]

#### **SOLUTION:**

n = 180 and p = 
$$\frac{1}{6}$$

Mean = np = 
$$(180)(\frac{1}{6})$$

$$Mean = 30$$

Hence, one would expect on average 30 threes.

# The Mean and Standard Deviation for a Binomial Distribution [3]

**EXAMPLE:** Twelve cards are selected from a deck and each card is replaced before the next one is drawn. Find the average number of diamonds.

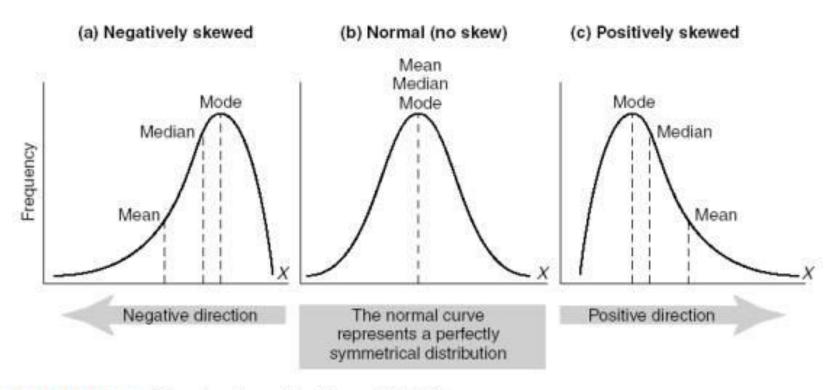

# The Mean and Standard Deviation for a Binomial Distribution [4]

#### **SOLUTION:**

In this case, n =12 and p = 
$$\frac{13}{52}$$

Mean = np = 
$$(12)(\frac{13}{52})$$

$$Mean = 3$$

#### FIGURE 15.6 Examples of normal and skewed distributions

## Negatively Skewed vs. Positively Skewed [1]

☐ When the variable is skewed to the left (i.e., <u>negatively skewed</u>), the mean shifts to the left the most, the median shifts to the left the second most, and the mode the least affected by the presence of skew in the data.

Therefore, when the data are **negatively skewed**, this happens:

mean < median < mode.

## Negatively Skewed vs. Positively Skewed [2]

□When the variable is skewed to the right (i.e., <u>positively skewed</u>), the mean is shifted to the right the most, the median is shifted to the right the second most, and the mode the least affected.

Therefore, when the data are **positively skewed**, this happens:

mean > median > mode

# Negatively Skewed vs. Positively Skewed [2]

You can use the following two rules to provide some information about skewness even when you cannot see a line graph of the data (i.e., all you need is the mean and the median):

- 1. Rule One. If the mean is less than the median, the data are skewed to the left.
- 2. Rule Two. If the mean is greater than the median, the data are skewed to the right.

# The Mean and Standard Deviation for a Binomial Distribution [3]

**EXAMPLE:** A die is rolled 180 times. Find the standard deviation of the number of threes.

# The Mean and Standard Deviation for a Binomial Distribution [4]

#### **SOLUTION:**

Standard deviation =  $\sqrt{npq}$ 

Standard deviation = 
$$\sqrt{180(\frac{1}{6})(\frac{5}{6})}$$

The standard deviation is 5

# The Mean and Standard Deviation for a Binomial Distribution [5]

Roughly speaking, most of the values fall within two standard deviations of the mean.

$$\mu - 2\sigma$$
 < most values <  $\mu + 2\sigma$ 

In the die example, we can expect most values will fall between

30 - 2\*5 < most values < 30 + 2\*5

20 < most values < 40

# The Mean and Standard Deviation for a Binomial Distribution [6]

**EXAMPLE:** An archer hits the bull's eye **80%** of the time. If he shoots **100** arrows, find the mean and standard deviation of the number of bull's eyes. If he travels to many tournaments, find the approximate range of values.

# The Mean and Standard Deviation for a Binomial Distribution [6]

#### **SOLUTION:**

$$\begin{array}{l} n=100,\,p=0.80,\,q=1-p=1-0.80=0.20\\ Mean=\mu=np=100\times0.80=80\\ Standard Deviation=\sigma=\sqrt{npq}\\ &=\sqrt{100\times0.80\times0.20}=4\\ \mu-2\sigma<\,most\,values<\mu+2\sigma\\ 80-8<\,most\,values<80+8\\ 72<\,most\,values<88 \end{array}$$

**Example:** The probability that a certain kind of component will survive a shock test is  $\frac{3}{4}$ . Find the probability that exactly **2** of the **next 4** components tested survive.

#### **Solution:**

Here n = 4

$$p = \frac{3}{4}$$

(probability of survive a shock test)

$$p + q = 1$$

$$q=1-p=1-\frac{3}{4}=\frac{1}{4}$$

Let x denotes number of components that survive a shock test

$$b(x; n, p) = {n \choose x} p^x q^{n-x}, x = 0, 1, 2, 3..., n$$

$$b\left(2;4,\frac{3}{4}\right) = {4 \choose 2}(\frac{3}{4})^2(\frac{1}{4})^{4-2} = \frac{27}{128} = 0.2109$$

### **Binomial Distribution [1]**

**EXAMPLE 1:** The probability that a patient recovers from a rare blood disease is **0.4**. If **15** people are known to have contracted this disease, what is the probability that

- (a) at least 10 survive
- (b) from 3 to 8 survive
- (c) exactly 5 survive

#### **SOLUTION**

(a) 
$$P(X \ge 10) = 1 - P(X < 10) = 1 - \sum_{x=0}^{x=9} b(x; 15,0.4) = 1 - .9662 = 0.033$$

(b) 
$$P(3 \le X \le 8) = \sum_{x=3}^{x=8} b(x; 15,0.4)$$
  
 $= \sum_{x=0}^{x=8} b(x; 15,0.4) - \sum_{x=0}^{x=2} b(x; 15,0.4)$   
(By using Table A.1of the Appendix for n = 1,2,..., 20, and selected values of p; from 0.1 to 0.9)  
 $= .9050 - 0.0271 = 0.8779$ 

### **Binomial Distribution [2]**

(c) 
$$P(X = 5) = \sum_{x=0}^{x=5} b(x; 15,0.4) - \sum_{x=0}^{x=4} b(x; 15,0.4)$$
  
= 0.4032 - 0.2173 = 0.1859

(By using Table A.1of the Appendix for n = 1,2,..., 20, and selected values of p; from 0.1 to 0.9)

**Conjectured:** Opinion or judgment based on inconclusive or incomplete evidence; guesswork

Or

An opinion or conclusion based on guesswork.

The commentators made various conjectures about the outcome of the next election.

## **Binomial Distribution [3]**

drinking wells in a certain rural community. In order to gain some insight into the true extent of the problem, it is determined that some testing is necessary. It is too expensive to test all of the wells in the area, so 10 are randomly selected for testing.

(a) Using the binomial distribution, what is the probability that exactly 3 wells have the impurity, assuming that the conjecture is correct?

(b) What is the probability that more than 3 wells are impure?

#### **Solution:**

(a) 
$$b(3; 10, 0.3) = \sum_{x=0}^{x=3} b(x; 10, 0.3) - \sum_{x=0}^{x=2} b(x; 10, 0.3)$$
  
= 0.6496 - 0.3828 = **0.2668**

(b) 
$$P(X > 3) = 1 - P(X \le 3)$$

$$= 1 - \sum_{x=0}^{x=3} b(x; 10, 0.3)$$

$$= 1 - 0.6496 = 0.3504$$

## **Binomial Distribution [3]**

**Example :** Consider the situation of the previous example. The "30% are impure" is merely a conjecture put forth by the area water board. Suppose 10 wells are randomly selected and 6 are found to contain the impurity. What does this imply about the conjecture? Use a probability statement.

**Solution:** We must first ask: "If the conjecture is correct, is it likely that we could have found 6 or more impure wells?"

$$P(X \ge 6) = 1 - P(X < 6) = \sum_{x=0}^{x=10} b(x; 10,0.3) - \sum_{x=0}^{x=5} b(x; 10,0.3)$$

- As a result, it is very unlikely (4.7% chance) that 6 or more wells would be found impure if only 30% of all are impure.
- ☐ This casts considerable doubt on the conjecture and suggests that the **impurity problem** is much **more severe**.

### **Binomial Distribution [4]**

**Example:** A family has 6 children. Find the probability P that there are

- (i) 3 boys and 3 girls.
- (ii) fewer boys than girls.

Assume that the probability of any particular child being a boy is 1/2.

#### **Solution:**

Here n = 6 and p = q = 1/2.

Let X denotes number of boys

(i) 
$$P(X = 3) = {}_{6}C_{3}(1/2)^{3}(1/2)^{3} = 20/64 = 5/16$$

(ii) There are fewer boys than girls if there are 0, 1 or 2 boys.

$$P(X \le 2) = {}_{6}C_{0}(1/2)^{0}(1/2)^{6} + {}_{6}C_{1}(1/2)^{1}(1/2)^{5} + {}_{6}C_{2}(1/2)^{2}(1/2)^{4}$$
$$= 11/32$$

Example Jury Selection In the case of Castaneda v. Partida it was noted that although 80% of the population in a Texas county is Mexican-American, only 39% of those summoned for grand juries were Mexican-American. Let's assume that we need to select 12 jurors from a population that is 80% Mexican-American, and we want to find the probability that among 12 randomly selected jurors, exactly 7 are **Mexican-Americans.** 

- a. Does this procedure result in a binomial distribution?
- **b.** If this procedure does result in a binomial distribution, identify the values of n, x, p, and q.

#### Solution a.

- 1. The number of trials (12) is fixed.
- 2. The 12 trials are independent. (Technically, the 12 trials involve selection without replacement and are not independent, but we can assume independence because we are randomly selecting only 12 members from a very large population.)
- 3. Each of the 12 trials has two categories of outcomes: The juror selected is either Mexican-American or is not.
- **4.** For each **juror selected**, the probability that he or she is **Mexican-American** is **0.8** (because 80% of this population is Mexican-American). That probability of **0.8 remains** the same for each of the **12 jurors**.

46

**b.** Having concluded that the given procedure does result in a binomial distribution, we now proceed to identify the values of n, x, p, and q.

- **1.** With **12 jurors** selected, we have n = 12.
- 2. We want the probability of exactly 7 Mexican-Americans, so x = 7.
- 3. The probability of success (getting a Mexican-American) for one selection is 0.8, so p = 0.8.
- **4.** The probability of failure (not getting a Mexican-American) is 0.2, so q = 0.2.
